**Abstract** *Perilla frutescens* was an annual herb considered as one of the “One Root of Medicine and Food”, and it was used widely for food and medical treatment. Its main active ingredients were volatile organic compounds (VOCs), but it was easily affected during drying and storage. The leaves, seeds and stems had shown differences in therapeutic effects, but the underlying reason remained unclear. In the present work, headspace-gas chromatography-ion mobility spectrometry

 Volatile organic compounds

(HS-GC-IMS) and headspace solid phase microextraction-gas chromatography-mass spectrometry (HS-SPME-GC-MS) were utilized to effectively and comprehensively analyze VOCs of fresh and dried *P. frutescens* between the leaves, stems and seeds. Meanwhile, chemometric analysis was applied to compare and identify characteristic volatile markers. As a result, 60 VOCs were identified by HS-GC-IMS and 115 VOCs were identified by HS-SPME-GC-MS from *P. frutescens*. 25 potential volatile markers were selected based on a combination model of orthogonal partial least squares discriminant analysis (OPLS-DA) and random forest (RF). The models could be used to analyze the variation between fresh and dried *P. frutescens* and distinguish the differences in different parts effectively and comprehensively. It was the first research regarding the method development of HS-GC-IMS and HS-SPME-GC-MS that comprehensively analyzes the VOCs characterization of fresh and dried *P. frutescens* in different parts and the findings obtained would evaluate the quality and provide a reference for further exploration of the edible and medicinal effects of *P. frutescens*.

## 1. Introduction

*Perilla frutescens* (L.) Britt. was a significant traditional Chinese medicine (TCM) with dual features of both nutrition and medical treatment that belongs to the Lamiaceae family and was extensively cultivated in East Asian countries such as Japan, India and China (Bachheti et al., 2014). It was used as an ornamental plant in gardens because of their specific leaf morphology and exceptional fragrance as well as in skin care products owing to their biological activities (Ahmed 2018). It was also used as a kitchen herb in salads, sushi, and soups and as a spice, garnish, or food colorant as well (Fujiwara et al., 2018, Ahmad 2022). In addition, *P. frutescens* was also used as a functional food which was considered an excellent alternative to fish oil nutritional supplement and a good source of vitamins and minerals (Ahmed 2018). It could even reduce the risk of cancer, cardiovascular disease and metabolic disorders such as breast cancer, obesity, type 2 diabetes and so on (Wang et al., 2020, Ahmad 2022). In Chinese traditional medicinal system, dried parts such as *P. frutescens* leaves, *P. frutescens* stems and *P. frutescens* seeds were considered as different drug and have different treatment effects (Liu et al., 2013). The leaves were introduced for treating respiratory and intestinal diseases such as cough, vomiting in pregnancy, cold, fever, poisoning from fish and crabs, and so on. The stems possessed the effect of curing vomiting and belching, epigastric pain, as well as threatened miscarriage, while the seeds were used to heal cough, wheezing, and constipation (Ahmed 2018). Modern pharmacological researchers had proved that *P. frutescens* possessed numerous effects of anti-bacterial, anti-inflammatory, anti-depression, analgesia, anti-mutagenic, anti-carcinogenic, preventing miscarriage, and so on (Dhyani et al., 2019, Ahmad 2022).

*P. frutescens* had a lot of complicated volatile organic components (VOCs). However, the variety and content of VOCs in processing, stored procedures and plant growth situations would be affected to a certain extent (Song et al., 2021). There were significant differences in VOCs content due to geography, harvesting time, etc. According to the chemotypes, it could be divided into ketone type, aldehyde type, phenol type, etc. (Zhang et al., 2009). *P. frutescens* containing a large amount of perilla ketone was reported to have potent acute toxicity and cardio-pulmonary toxicity for experimental animals and livestock (Yu et al., 2017). Therefore, it is important to comprehensively characterize VOCs in three different parts (seeds, leaves and stems) of fresh and dried *P. frutescens*. Previous studies in VOCs identified mostly used two-dimensional gas chromatography (GC × GC), gas chromatography mass spectrometry (GC-MS), electronic noses (e-nose) and gas chromatography-olfactometry-mass spectrometry (GC-O-MS) (Franchina et al., 2019, Li et al., 2022). GC-O-MS could screen the important aroma-active compounds of complex samples. But it was difficult to satisfy the rapid detection of volatile compounds because of the long sample pre-processing operation time (Song and

Liu 2018). Although e-nose was a relatively fast assessment detection system that possesses simple sample pretreatment and non-destructive features, the repeatability and stability were easily influenced by environmental factors and low accuracy (Zhou et al., 2017). GC × GC was a powerful precision analytical technique to study complex samples (Aspromonte et al., 2019). Its high resolution was not easy to achieve by GC-MS and GC-MS was applied more widely in practical applications. GC-MS was a detection technology applied to the separation and identification of complex component. It was provided with the advantages of safety, accuracy and high separation ability (Yin et al., 2021). Furthermore, the introduction of headspace solid-phase microextraction (HS-SPME) that integrates extraction, concentration, desorption, and sampling had greatly improved the complex procedures of GC-MS sample pretreatment (e.g., traditional essential oil extraction), and achieved efficient determination of VOCs without damaging the sample (Zanella et al., 2021). HS-GC-IMS was an emerging technique with high molecular specificity and sensitivity for detecting in the field of small molecular weight VOCs based on the difference in migration velocity of different gas phase ions in an electric field. The technology had the advantages of easy operation, affordability, and nondestructive analysis (He et al., 2020, Yin et al., 2021). HS-GC-IMS detected smaller VOCs particles than HS-SPME-GC-MS. Combining HS-SPME-GC-MS and HS-GC-IMS was able to promote detection efficiency and implement the comprehensive characterization of VOCs. To our knowledge, no research has been conducted to compare and comprehensively analyze VOCs of the different parts of fresh and dried *P. frutescens* combining HS-SPME-GC-MS and HS-GC-IMS.

Therefore, the aim of this study was to explore the differences in VOCs in different parts of *P. frutescens* and the effect of natural drying on VOCs in order to better understand the characteristic VOCs in *P. frutescens*. HS-GC-IMS and HS-SPME-GC-MS were used to establish the characteristic volatile fingerprints and investigate the differences of VOCs among three parts of fresh and dried *P. frutescens*. Multivariate statistics were used to investigate the key substances in three different parts of fresh and dried *P. frutescens*, which provided reference evidence for the development of functional food and phytomedicines.

## 2. Materials and methods

### 2.1. Samples and reagents

*P. frutescens* samples were collected from the botanical gardens of Tianjin University of Traditional Chinese Medicine where the collection district was divided into five areas. The samples were made an identification by Professor Lijuan Zhang from Tianjin University of Traditional Chinese Medicine. Then, each sample was immediately divided into two

parts. One part was placed in a refrigerator (Haier Co., Ltd, Shandong, China) at  $-4^{\circ}\text{C}$  to maintain its freshness as fresh *P. frutescens* samples. The other part was used as dried *P. frutescens* sample after air-desiccated for six days in the shade, and then were sealed and stored under normal temperature. So, there were a total of 30 batches samples containing different parts (stems, leaves, seed) of fresh and dried. All samples were stored in the laboratory of Tianjin University of Traditional Chinese Medicine.

N-ketone C4-C9 standard mix for HS-GC-IMS was purchased from Sinopharm Chemical Reagent Co., Ltd. (Beijing, China). N-alkane C8-C20 standard was got from Sigma-Aldrich Chemical Co., Ltd. (Missouri USA) as external references for HS-SPME-GC-MS. Reference standards of perilla ketone (CAS: 553-84-4), caryophyllene (CAS: 87-44-5), caryophyllene oxide (CAS: 1139-30-6), linalool (CAS: 78-70-6), 1-octen-3-ol (CAS: 3391-86-4), humulene (CAS: 6753-98-6) and citral (CAS: 5392-40-5) were obtained from Shanghai Yuanye Bio-Technology Co., Ltd. (Shanghai, China). Seven standards were diluted with ethyl acetate to form a mixed standard (perilla ketone: 1.5 mg/mL, caryophyllene: 0.4  $\mu\text{L}/\text{mL}$ , caryophyllene oxide: 0.112 mg/mL, linalool: 1  $\mu\text{L}/\text{mL}$ , 1-octen-3-ol: 1  $\mu\text{L}/\text{mL}$ , humulene: 0.4  $\mu\text{L}/\text{mL}$  and citral: 1  $\mu\text{L}/\text{mL}$ ).

## 2.2. HS-GC-IMS analysis

The experiment was analyzed on the HS-GC-IMS apparatus (Flavourspec®, G.A.S, Dortmund, Germany) with an autosampler (CTC Analytics AG, Zwingen, Switzerland) and the GC was provided with a FS-SE-54-CB-1 (CS-Chromatographie Service GmbH, Germany) capillary column (15 m  $\times$  0.53 mm ID, 0.5  $\mu\text{m}$ ). The fresh samples were thinly grated while the dried samples were pulverized into powder (40-mesh sieve). First, 0.3 g of sample was weighed into a 20 mL headspace glass sampling bottle (Zhejiang HAMAG technology, Ningbo, China), and incubated at  $80^{\circ}\text{C}$  for 20 min with an incubation speed of 500 rpm. Subsequently, headspace samples (500  $\mu\text{L}$ ) were automatically injected into the injector ( $85^{\circ}\text{C}$ ) with splitless mode and then driven into the FS-SE-54-CB-1 capillary column of  $45^{\circ}\text{C}$  isothermal conditions through nitrogen of 99.99% purity. And its programmed flow rate was started at 2 mL/min for 2 min, then increased to 10 mL/min within 15 min, increased to 100 mL/min over 25 min and increased to 120 mL/min over 30 min. The flow rate of purified nitrogen (99.999% purity) was at the rate of 150 mL/min as the drift gas. The analytes following GC separation and elution at  $75^{\circ}\text{C}$  were driven into the IMS ionization chamber. Finally, the analytes were ionized by 3H ionization source with 300 MBq activity under the positive ion mode. The generating ions were transferred into the drift tube of 9.8 cm in length. The IMS drift tube worked at an electric-field of 5 kV and  $45^{\circ}\text{C}$  isothermal conditions. All analyses were taken thrice. N-ketone C4-C9 standard mix was used to calculate the retention index (RI) of each compound as external references.

## 2.3. HS-SPME-GC-MS analysis

HS-SPME-GC-MS analysis was implemented by an Agilent 7890B instrument (Agilent, CA, USA) equipped with an Agilent 7000D mass spectrometry detector and GC autosampler

system. The GC was fitted with a HP-5MS elastic quartz capillary column (30 m  $\times$  0.25 mm  $\times$  0.25  $\mu\text{m}$ , 19091S-433, J&W Scientific, Folsom, CA, USA). SPME (Polydimethylsiloxane/Carboxen/divinylbenzene 50/30  $\mu\text{m}$  phase thickness (PDMS/CAR/DVB) fiber (supelco, Bellefonte, Penn.) was installed on Multipurpose sampler (Gerstel, GER). The fresh samples were thinly grated while the dried samples were pulverized into powder (40-mesh sieve). Briefly, 0.3 g of sample was weighed into a 20 mL headspace glass sampling bottle (Zhejiang HAMAG technology, Ningbo, China) and incubated at  $60^{\circ}\text{C}$  incubation temperature for 5 min. Subsequently, the SPME fiber needle inserted into the headspace glass sampling bottle for extraction for 10 min at  $60^{\circ}\text{C}$ . Then, the fiber needle immediately plugged into the heated injection port at desorption for 5 min ( $250^{\circ}\text{C}$ , splitless mode). The flow rate of helium (> 99.999%) as the carrier gas was 1 mL/min. The GC column temperature was programmed temperature as follows: initially programmed at  $40^{\circ}\text{C}$  for 2 min, at  $7^{\circ}\text{C}/\text{min}$  to  $62.5^{\circ}\text{C}$ , at the rate of  $20^{\circ}\text{C}/\text{min}$  to  $72.5^{\circ}\text{C}$ , at  $2^{\circ}\text{C}/\text{min}$  to  $85^{\circ}\text{C}$ , rose to  $145^{\circ}\text{C}$  at rate of  $5^{\circ}\text{C}/\text{min}$ , then at  $2^{\circ}\text{C}/\text{min}$  to  $150^{\circ}\text{C}$ , at  $5^{\circ}\text{C}/\text{min}$  to  $155^{\circ}\text{C}$ , at  $7^{\circ}\text{C}/\text{min}$  to  $170^{\circ}\text{C}$ , eventually, at  $20^{\circ}\text{C}/\text{min}$  to  $250^{\circ}\text{C}$  held for 5 min. The GC total running time was 45.393 min. The MS was operated in electron ionization (EI) mode at ionizing energy of 70 eV. The injection port and ion source temperature were set at  $250^{\circ}\text{C}$  and  $230^{\circ}\text{C}$ , respectively. The quadrupole temperature was  $150^{\circ}\text{C}$ . The mass spectra (MS1 full scan mode) was scanned from 50 to 600  $m/z$ . All samples were performed in double. N-alkane C8-C20 standard was used to calculate RI of each compound as external references.

## 2.4. Data analysis

VOCs detected by HS-GC-IMS were identified by Laboratory Analytical Viewer (LAV) according to RI and drift time (Dt) and the fingerprint was established by Gallery Plot. VOCs detected by HS-SPME-GC-MS were tentatively identified from the standard NIST17 (matching degree greater than 700, RI) and reference compounds. Principal component analysis (PCA) and hierarchical clustering analysis (HCA) analyses were conducted by Origin 2021 software. SIMCA 14.1 was used to build the model of orthogonal partial least squares discrimination analysis (OPLS-DA). The online website MetaboAnalyst 5.0 was employed to build the Random Forest (RF) model.

## 3. Results and discussions

### 3.1. The characteristic VOCs of fresh and dried *P. frutescens*

#### 3.1.1. Differences of VOCs between fresh and dried *P. frutescens* by HS-GC-IMS

HS-GC-IMS analysis was the latest non-targeted and rapid analytical technique which had great potential for detecting small-molecule (Chen et al., 2021). For exploring the differences of small-molecule VOCs among fresh and dried *P. frutescens*, the small-molecule VOCs were detected by HS-GC-IMS. In the present study, 60 small-molecule VOCs were identified according to RI and Dt in all *P. frutescens* samples by HS-GC-IMS (Supplementary Information, Table A.1 and Fig. S1). Due to the adduct formation between partial molecules

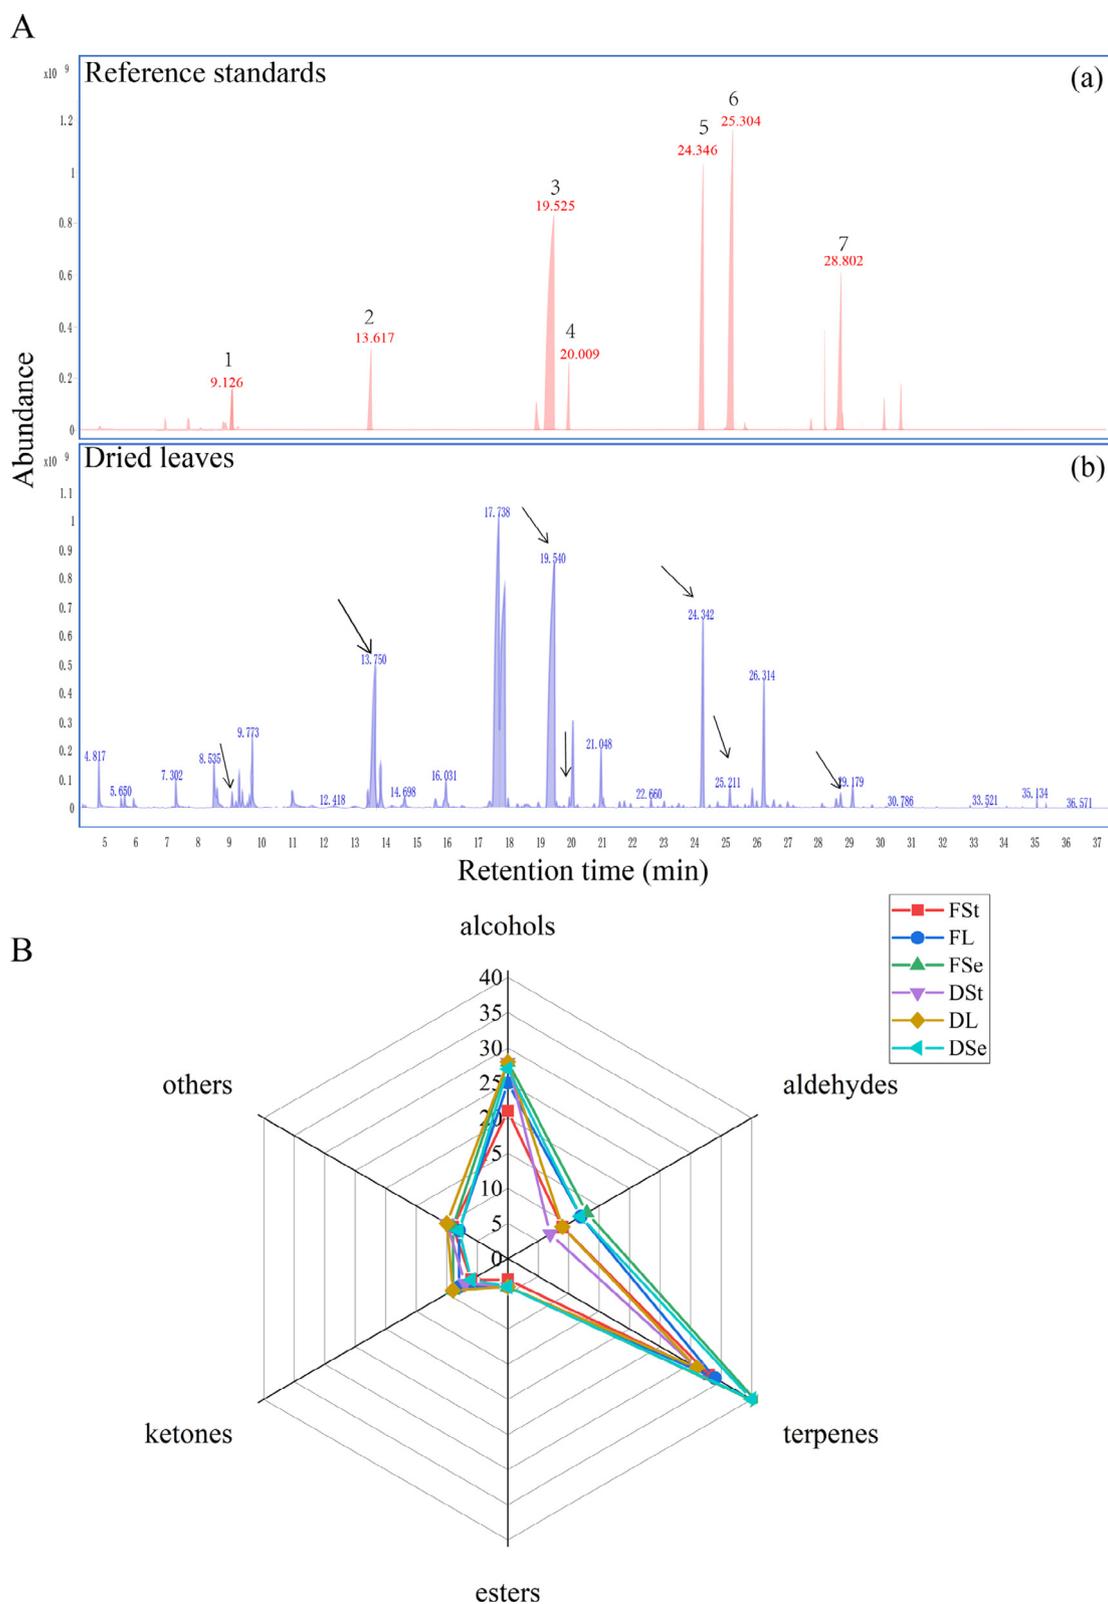

and reactant ions, a single VOCs with high concentration or higher proton affinity than that of water could form multiple signals presenting as dimer or polymer (Zhang et al., 2021). Therefore, the identified components included both dimers and monomers. However, the differences among fresh and dried *P. frutescens* could not be quickly identified by table. Therefore, the fingerprints were established between fresh samples and dried samples in the same part (Fig. 1A&B&C). The color represented the peak intensity. The peak intensity increased from blue to white and then to red. The compositional differences were evident between fresh and dried samples in fingerprints. 22 small-molecule VOCs (heptan-2-ol, vanillin, benzyl alcohol, etc.) only were identified in fresh stem (Fig. 1A, a). Conversely, 10 small-molecule VOCs (e.g., 4-methylguaiacol, coumarin, 4-ethylphenol, etc.) were recognized only in dried stems (Fig. 1A, b). Compounds “Unknown” were unidentified compound. After comparing fresh and dried *P. frutescens* stems, it was found that fresh stems had many special components that dried stems do not have. For example, benzothiazole of fresh stems had anticancer, anti-inflammatory, analgesic antidiabetic, etc. (Das et al., 2022), which suggested that future research could develop related products for fresh *P. frutescens* stems. 18 small-molecule VOCs (p-cymen-7-ol, nerol, eugenol, etc.) were only identified in fresh leaves (Fig. 1B, c). Nerol and eugenol with antibacterial and antioxidant properties had long been used in food and cosmetology (Wang et al., 2019, Ulanowska and Olan 2021). 12 small-molecule VOCs were only identified in dried leaves, such as neryl acetate, ethyl 3-phenylpropanoate, and so on (Fig. 2B, d). Vanilla was detected both in fresh and dried leaves, which was the world’s most popular flavor in food, cosmetics, and medicine (Arya et al., 2021). 5 small-molecule VOCs ( $\alpha$ -terpineol, 2-acetylthiazole, etc.) were identified exclusively in dried seeds (Fig. 1C, e), while geraniol and phenyl ethyl alcohol were just recognized in fresh seeds (Fig. 1C, f). Geraniol were regarded as good natural preservatives on account of antibacterial and antioxidant (Lin et al., 2021). After drying, the components existing in the fresh samples disappeared in the dried sample, and many new components were produced in the dried samples (Fig. 1A&B&C), especially in the stems and leaves samples, which demonstrated those compounds were sensitive to drying process and were decomposed or degraded. Besides, these components may contribute to the corresponding aroma between fresh and dried *P. frutescens*. The signal strength represented the concentration of flavor molecules (Fig. 1A&B&C) of HS-GC-IMS, the white color indicated the lower concentration while the red color box showed higher and the darker the color gets, the higher the concentration of fingerprint plots (Chen et al., 2021). Compared to dried samples (seeds, leaves and stems), fresh samples (seeds, leaves and stems) seemed to have a stronger signal intensity. The changes of signal intensities of small-molecule VOCs were due to the chemical reactions (Maillard reaction, interaction between different molecules and degradation of macromolecules) during drying (Guo et al., 2018). Fresh *P. frutescens* was more suitable as flavorings or vegetables to use because it had a strong flavor concentration. Besides, the small-molecule VOCs that had been identified were classified into six ingredient categories (Fig. 1D). Alcohols (11 components) and others (7 components) were most found in fresh *P. frutescens* leaves. Esters (9 components) were most found in dried *P. frutescens* leaves.

Ketones (6 components) mainly focused on dried *P. frutescens* seeds. Aldehydes (3 components) were relatively abundant in fresh *P. frutescens* seeds. Thus, the aroma of *P. frutescens* were more derived from alcohols and Esters. In the current study, most of the small molecules contained in *P. frutescens* had strong oxidative and antibacterial bioactivities, making it a potential ingredient for functional food development. Unfortunately, there were still many small-molecule VOCs of *P. frutescens* that had not yet been identified. Therefore, the IMS database needed to be further supplemented in future researches.

### 3.1.2. Differences of VOCs between fresh and dried *P. frutescens* by HS-SPME-GC-MS

HS-SPME-GC-MS was used widely and effectively for analyzing VOCs. In order to explore comprehensively VOCs between fresh and dried *P. frutescens*, HS-SPME-GC-MS was performed. A total of 115 VOCs were identified by HS-SPME-GC-MS (Supplementary Information, Table A.2). Seven compounds had passed standard validation (Fig. 2A, a), and the remaining components had been identified through literatures, database, and RI. The components detected by HS-SPME-GC-MS were more than HS-GC-IMS. The total ion chromatograms (TIC) of all *P. frutescens* samples were shown in Supplementary Information (Supplementary Information, Fig. S2). Elsholtzia ketone, cuminaldehyde, perilla ketone, caryophyllene, and linalool with relatively high content (Fig. 2A, b) possessed pharmacological activities for cardiovascular, respiratory systems and tumor cells (Ahmed 2018, Chen et al., 2020). After natural shade drying, these VOCs displayed change to some extent. Compared to the fresh *P. frutescens* stems, a significant increase in the content of elsholtzia ketone, perilla ketone, caryophyllene, and linalool was found in the dried *P. frutescens* stems. Compared with the fresh *P. frutescens* leaves, the contents of perilla ketone, caryophyllene, and linalool were increased in all samples of dried *P. frutescens* leaves, but elsholtzia ketone and cuminaldehyde were decreased in dried *P. frutescens* leaves excluding sample 4 which had a slight increase. Elsholtzia ketone and cuminaldehyde were decreased in sample 5 and increased in the remaining dried *P. frutescens* seeds compared with the fresh *P. frutescens* seeds, whereas caryophyllene was decreased except for sample 5. Two other compounds (perilla ketone and linalool) were both increased and decreased between different batches of dried *P. frutescens* seeds. Interestingly, elsholtzia ketone and cuminaldehyde content seemed to exhibit synergistic effects after shade drying whether leaves and stems or seeds of *P. frutescens*. The differences may be a factor of dried *P. frutescens* as medicine. Some VOCs such as (*R*)-l-perillaldehyde,  $\alpha$ -farnesene and *trans*-2-hexenal were only detected in dried stems. Conversely, some VOCs such as (*R*)-cuparene, beta-elemene and citral were only identified in fresh stems. Cis-linalool oxide, (*R*)-l-perillaldehyde and  $\alpha$ -cubebene were just detected from dried leaves while butylated hydroxytoluene,  $\alpha$ -longipinene, and 2-methylbutyraldehyde were only tested from fresh leaves. 1-(6,6-dimethylbicyclo[3.1.0]hex-2-en-2-yl)-ethanone and ylangenol were only found in the dried seeds. Conversely, some ingredients (e.g. 3-carene,  $\beta$ -guaiene, egomaketone, etc.) were only detected in the fresh seeds. The VOCs formed after drying may be attributed to precursors in fresh samples being degraded, isomeric species or oxidation

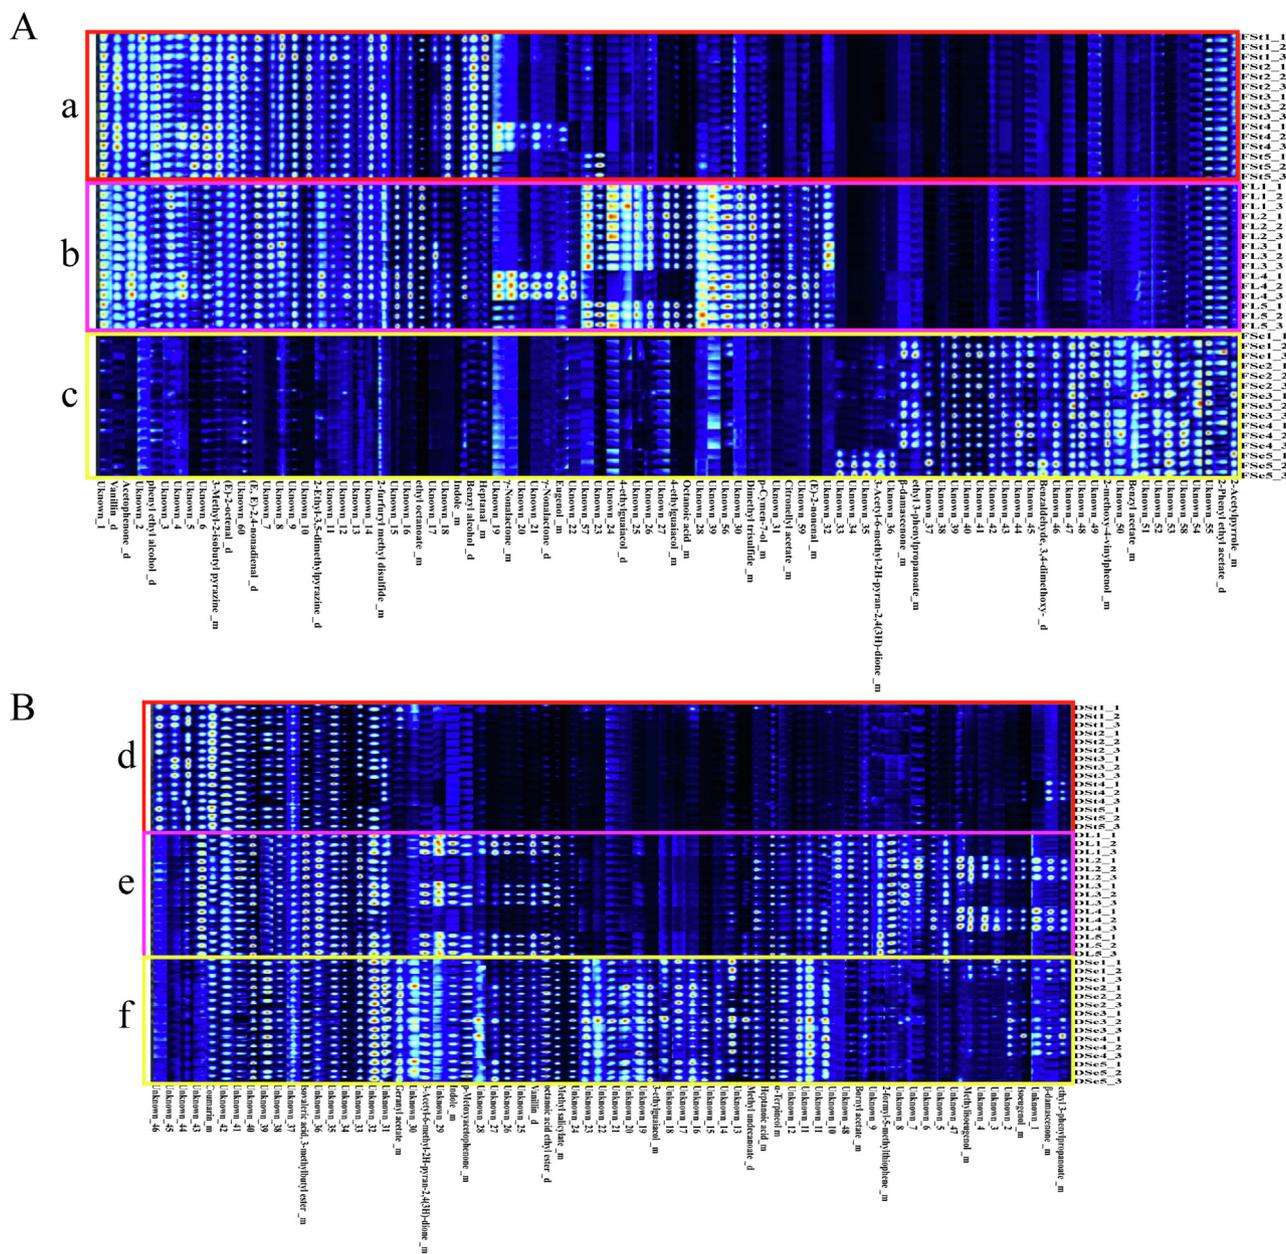

**Fig. 2** The total ion chromatograms (TIC) (A) and radar chart (B) of the fresh and dried *P. frutescens* from HS-SPME-GC-MS. (A): The total ion chromatograms of mixed standard chemicals (a) and dried *P. frutescens* leaves samples (b). 1: 1-Octen-3-ol; 2: Linalool; 3: Perilla ketone; 4: Citral; 5: Caryophyllene; 6: Humulene, 7: Caryophyllene oxide. (B): Component classification identified by HS-GC-IMS HS-SPME-GC-MS detected. Fst: fresh stems, FL: fresh leaves, FSe: fresh seeds, DSt: dried stems, DL: dried leaves, DSe: dried seeds.

reactions during the drying process(Song et al., 2021). Furthermore, small-molecule VOCs detected by HS-GC-IMS may be involved in synthesis and conversion processes of the aforementioned compounds detected by HS-SPME-GC-MS. For example, limonene could produce  $\alpha$ -terpineol by biotransformation(Molina et al., 2019). Terpenes were relatively abundant in fresh and dried *P. frutescens* (Fig. 2D). Terpenes were a vital member of the VOCs safeguarding plants against pests, diseases, and weeds, and also offered a wide range of prospects in the pharmaceutical, food, cosmetic, and flavoring industries(Ninkuu et al., 2021).

### 3.2. The characteristic VOCs of three parts of fresh and dried *P. frutescens*

#### 3.2.1. Differences of VOCs in three parts of fresh or dried *P. frutescens* by HS-GC-IMS

Dried parts such as leaves, stems and seed were regarded as different drugs from ancient times to the present, but the underlying reason remains unclear. The fingerprint profiles form by HS-GC-IMS (Fig. 3) indicated there was distinct variability among different parts of *P. frutescens*. Among the different parts of fresh *P. frutescens*, the part with the largest

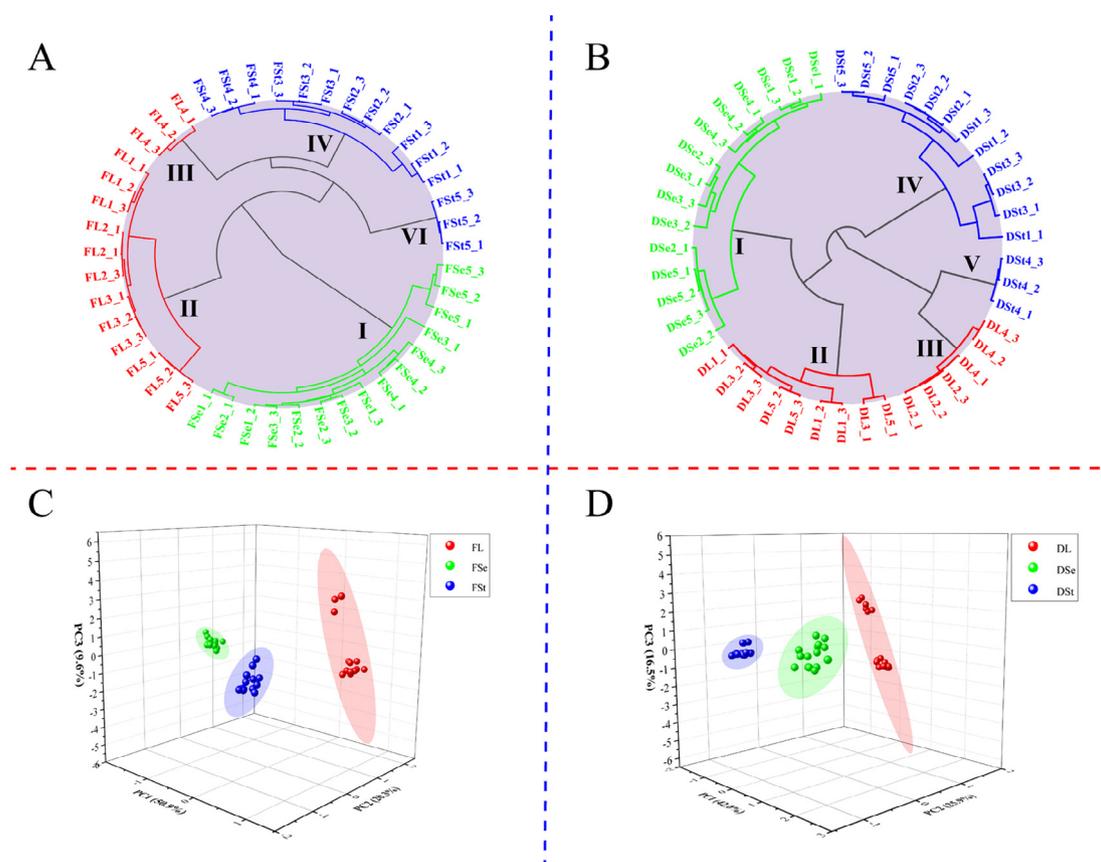

**Fig. 3** Fingerprints among three different parts of *P. frutescens* from HS-GC-IMS. (Each row stands for a selected signal peak in one sample and each column stands for a signal peak of a compound in a different sample). Fst: fresh stems (a), FL: fresh leaves (b), FSE: fresh seeds (c), DSt: dried stems (d), DL: dried leaves (e), DSE: dried seeds (f). (A) Different parts of fresh *P. frutescens*, (B) Different parts of dried *P. frutescens*.

amount and content of components was the fresh leaves (Fig. 3A, b), and the least was the fresh seeds (Fig. 3A, c). The flavor concentration of *P. frutescens* leaves was significantly higher, making them one of the favorite vegetables. The researches on different parts of fresh *P. frutescens* were very meaningful and could promote the development from multiple perspectives in the food field. Among the different parts of dried *P. frutescens*, the part with the largest number of components was the dried seeds (Fig. 3B, f), and the least was the dried stems (Fig. 3B, d). The differences in the amount and content of components in different parts of dried *P. frutescens* may be one of the reasons why different parts (seeds, leaves and stems) of *P. frutescens* as different drugs from the results (Fig. 3B). After the dataset was reduced dimensionality, principal component analysis and hierarchical cluster analysis (HCA: Fig. 4A&B) and (PCA: Fig. 4C&D) were carried out for chemometric analysis. Linkage method of HCA was average-link. Correlation was selected as type of distance. As displayed by the results of HCA (Fig. 4A&B), all fresh samples could be divided into three groups (I, II and IV) which correspond to the seeds, leaves and stems except for two of the samples (stem 5 and leaves 4) was misassigned (Fig. 4A). Meanwhile, other dried samples were clustered into three major clusters (I, II and IV) according to three medicinal parts (seeds, leaves and stems) although three samples of stem 4, leaves 4 and leaves 5 were not clustered into corresponding clusters (Fig. 4B). The result of PCA (Fig. 5C: PC1:50.9%, PC2:20.3%, PC3:9.6%; Fig. 4d: PC1:40 %, PC2:25.9%,

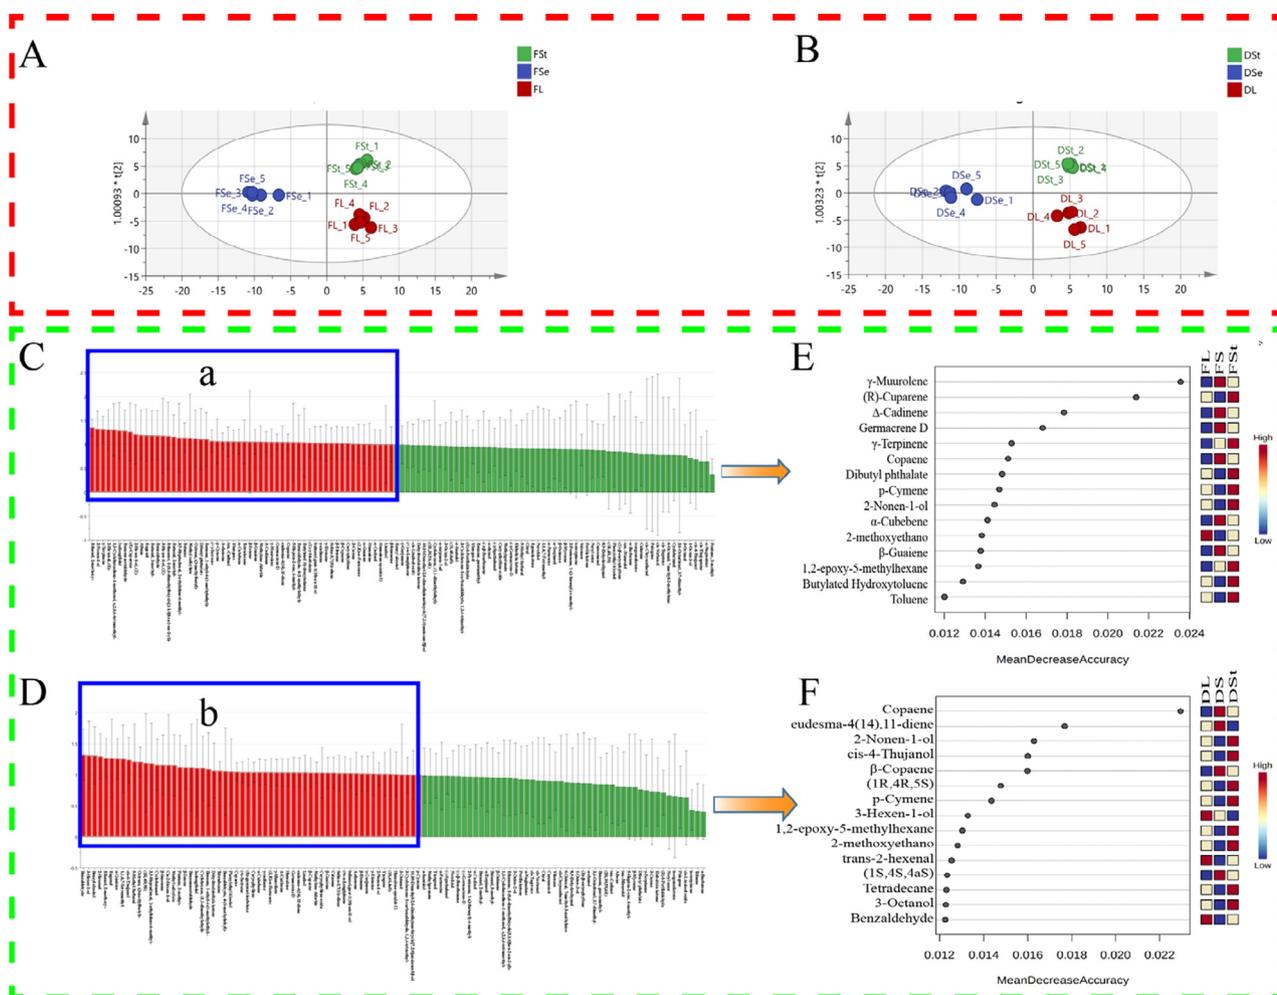

PC3:16.5%) was similar to HCA, but HCA relatively achieved better results. Overall, fingerprint profiles, PCA and HCA indicated that VOCs of small molecules in *P. frutescens* from different parts (leaves, stems and seeds) showed apparent differences. At present, some small-molecule VOCs had been reported to contribute to anti-cancer, such as geraniol, benzothiazole, geranyl acetate, and so on (e Silva et al., 2022). These small-molecule VOCs differences may be associated with the treatment of different kinds of diseases. Thus, the small-molecule VOCs of *P. frutescens* in pharmacological studies deserved further investigation. Interestingly, although all samples came from the botanical gardens, there were certain differences between batches indicating that using HS-GC-IMS was able to detect subtle differences, which the instrument provided a reference for quality control of *P. frutescens*. Meanwhile, *P. frutescens* had genetic instability and easily mated with closely related species to form similar morphology, but there were obvious differences in chemical composition (Hu et al., 2010). Thus, it also suggested more samples were necessary to explore the cultivation conditions, harvesting time, and processing conditions of high-quality *P. frutescens* to guarantee stable quality.

### 3.2.2. Differences of VOCs of three parts in fresh or dried *P. frutescens* by HS-SPME-GC-MS

Although there were no significant differences in the types of VOCs identified by HS-SPME-GC-MS, differences in content of components of different parts were observed (Supplemen-

(C)&(D) The variable importance for the projection (VIP) predictive of the VOCs (a&b were VIP value greater than 1). (E) significant features of different parts of the fresh. (F) significant features of different parts of the dried. Additionally, (1R,4R,5S): (1R,4R,5S)-1,8-dimethyl-4-(prop-1-en-2-yl) spiro[4.5]dec-7-ene. (1S,4S,4aS): (1S,4S,4aS)-1-isopropyl-4,7-dimethyl-1,2,3,4,4a,5-hexahydronaphthalene. (2R,3S,5S,6R): (2R,3S,5S,6R)-2,5-bis(4-Methoxyphenyl)-3,6-dimethyl-1,4-dioxane-rel- 1,1,4,7-Tetramethyl: 1,1,4,7-Tetramethyl-1a,2,3,4,6,7,7a,7b-octahydro-1H-cyclopropa[e]azulene.

tary Information, Fig.S2 and TableA2). Since there was genetic diversification and varied the content of components in VOCs, previous studies based on the main component content of essential oil divided into the following chemotypes: perillaketone (PK), perillaldehyde (PA), elsholtziaketone (EK), citral (C), phenylpropanoids (myristicin, dillapiole, elemicin) (PP), D-limonene and piperitone (DLP),  $\beta$ -caryophyllene myristicine (MT), perillene (PL) and piperitenone types (PT) (Kimura and Ito 2020). In this study, cuminaldehyde, elsholtzia ketone, perilla ketone and caryophyllene were mainly detected. The content of these components was ranked in the top five of the total VOCs in most of the samples either fresh or dried *P. frutescens*. Thus, there were two chemotypes identified, including PK-type and EK-type according to the main VOCs in the HS-SPME-GC-MS data. Besides, cuminaldehyde made up the largest content of component in some samples, which had been reported that according to a new classification of five essential oils based on cluster analysis of Euclidean distance, it was divided into fifth categories (EK chemotypes)(Wei

et al., 2007). Therefore, the results of the current study supported with classification finding of Euclidean distance analysis and provided a scientific reference for EK chemotypes. Chemotypes of *P. frutescens* were related to the harvest period, sowing period and growing environment(Ghimire et al., 2017). Therefore, the result appeared variations of these VOCs between batches and had two chemotypes in the collection place.

Different parts of *P. frutescens* had been used in different medicine clinically. In order to further explore the different VOCs among different parts and screen out suitable volatile markers, the study combined orthogonal partial least squares discriminant analysis (OPLS-DA) and the Random Forest (RF) for analysis. The RF was a supervised method to handle high-dimensional data. The model displayed the best overall performance on volatile markers-selected (Chen et al., 2013). OPLS-DA was commonly used for visualizing high dimensional data and discriminant analysis of latent metabolites related to metabolic changes(Qi et al., 2020), which proved

to be powerful tools in qualitative data analysis. Moreover, the variable importance of the projection (VIP) in OPLS-DA was formed by measuring variables with scores.  $VIP \geq 1$  was used to identify the variables important to the model and were generally considered to be important variables. The larger the VIP value, the more important the variable to the divergence was between different parts. Meanwhile,  $VIP \geq 1$  was considered to be a significant factor for samples classification (Galindo-Prieto et al., 2014). In the study, two HS-SPME-GC-MS datasets (different parts of fresh *P. frutescens* and different parts of dried *P. frutescens*) were calculated by SIMCA 14.1 software based on the OPLS-DA model respectively (Fig. 5). All *P. frutescens* samples could be divided into three groups according to the different medicinal parts (seeds, leaves and stems) whether fresh (Fig. 5A) or dried *P. frutescens* (Fig. 5B), which indicated that differences existed among three parts. The explanatory and predictive abilities of the models were evaluated from  $R^2$  and  $Q^2$ . And the closer  $R^2$  and  $Q^2$  were to 1, the better fitness of the model was (Wang et al., 2019). The  $R^2$  and  $Q^2$  of the two OPLS-DA models were greater than 0.9 ( $R^2 = 0.978$ ,  $Q^2 = 0.915$  and  $R^2 = 0.965$ ,  $Q^2 = 0.92$ ), which indicated excellent explanatory and predictive effects of the OPLS-DA model for the classification of different parts of *P. frutescens*. Based on the criteria of  $VIP \geq 1$ , 56 (a) and 60 (b) important variables were selected in different parts of fresh and dried *P. frutescens* respectively from the VIP plot of OPLS-DA (Fig. 5C&D). To further explore favorable volatile markers from these essential variables, a RF algorithm was used to build RF model. The classification trees of RF model were set as 1000. During trees building, one-third of the samples were used as training data and the remaining samples were used as test data to get a judicial assessment of the out-of-bag (OOB) error. Theoretically, the cross-verification was conducted internally in the RF algorithm between the operation by the OOB dataset. The lower OOB error was a criterion of classifier quality (Bulgarevich et al., 2018). After several trees, the cumulative OOB error rates decreased to 0.0667 in different parts of fresh *P. frutescens* and to 0 in different parts of dried *P. frutescens*. Fig. 5E&F showed the first fifteen significant features in the ranking through the RF model.  $\gamma$ -muurolene,  $\alpha$ -cubebene,  $\Delta$ -cadinene, copaene,  $\beta$ -guaiene and germacrene D were more abundant in fresh seeds (Fig. 5E) with antibacterial and antioxidant, which were suitable for exploitation in various skin-care products (Bahadori et al., 2017, Falleh et al., 2020). (*R*)-cuparene,  $\gamma$ -terpinene, dibutyl phthalate, *p*-cymene, 2-nonen-1-ol, 1,2-epoxy-5-methylhexane, butylated hydroxytoluene and toluene were identified as significant volatile markers in fresh stems (Fig. 5E), in which  $\gamma$ -terpinene and *p*-cymene with anti-inflammatory and antioxidant effects had synergistic antibacterial effect (Sousa et al., 2022). Only 2-methoxyethanol was screened as volatile marker of the fresh leaves (Fig. 5E). Most of the volatile markers of fresh *P. frutescens* had antibacterial effects, which may be beneficial for the development of functional food related to oral cavity. Meanwhile, dried leaves had volatile markers of 3-hexen-1-ol, benzaldehyde and *trans*-2-hexenal, dried seeds had  $\beta$ -copaene, copaene, eudesma-4(14),11-diene and (1*S*,4*S*,4*aS*)-1-isopropyl-4,7-dimethyl-1,2,3,4,4*a*,5-hexahydronaphthalene, and dried stems had 2-nonen-1-ol, *cis*-4-thujanol, (1*R*,4*R*,5*S*)-1,8-dimethyl-4-(prop-1-en-2-yl)spiro[4.5]dec-7-ene, *p*-cymene, 1,2-epoxy-5-methylhexane,

tridecane, 3-octanol and 2-methoxyethanol (Fig. 5F). *P*-cymene exhibited remarkable antiproliferative potential against several cancer cell lines such as human cervical cancer, human non-small cell lung cancer (NSCLC) A549 and A427 cell lines (Balahbib et al., 2021). These potential volatile markers provided the reference for studying differences in therapeutic effect.

#### 4. Conclusion

In the present study, the experiment analyzed qualitatively and relatively quantitatively VOCs of fresh and dried *P. frutescens* accessing to HS-GC-IMS and HS-SPME-GC-MS, as well as using multivariate statistics screened for related volatile markers in different parts. The results demonstrated that the differences of VOCs in the stems, the leaves and the seeds of fresh and dried *P. frutescens* were obviously observed according to HS-GC-IMS and HS-SPME-GC-MS. Thus, attention should be paid to distinguishing different parts of *P. frutescens*, which provided a scientific reference for the different applications of different parts of *P. frutescens* in clinical treatment. In small-molecule flavor, there were fewer shared VOCs between dried and fresh *P. frutescens* and the content of VOCs was reduced in dried samples. Many characteristic VOCs were detected in fresh and dried *P. frutescens*. These results were helpful for the development of unique functional food. In VOCs detected by HS-SPME-GC-MS, the content of most of the components was increased during the process of drying. Comprehensive analysis of fresh and dried *P. frutescens* could acquire more information which was beneficial for future development and application. In addition, the RF model screened out 25 important volatile markers such as *trans*-2-hexenal, *p*-cymene and  $\alpha$ -cubebene, etc. Therefore, the current study could provide a reference for further exploration in the field of the food and TCM of *P. frutescens*.
