**Abstract** Osteoblast cell injury is a type of degenerative disorder characterized by osteolysis. Levan polysaccharide is an active component of *Erwinia herbicola*, which shows potential anti-inflammatory and antioxidant properties. However, the protective effects of levan on lipopolysaccharide (LPS)-induced inflammatory and oxidative stress injury in osteoblast cells as an *in vitro* model of osteolysis remain largely unknown. The present study aimed to explore the functions of levan in LPS-triggered inflammation and oxidative stress in osteoblast cells (MC3T3-E1). The protective effects of levan on LPS-induced inflammatory and oxidative stress responses in MC3T3-E1 cells were assessed by quantification of superoxide dismutase (SOD) and catalase (CAT) activity as well as enzyme-linked immunosorbent assay (ELISA) for determination of interleukin-6 (IL-6) and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ). Also, the key signaling pathway of ChemR23 was determined by qPCR analysis. Results showed that levan significantly alleviated LPS-induced deactivation of SOD and CAT activity. Levan also downregulated the expression of IL-6, TNF- $\alpha$ , and ChemR23 at mRNA level. These findings indicated that levan may protect MC3T3-E1 cells against

## 1. Introduction

Pathogenic stimuli can irreversibly damage vital molecules such as nucleic acids, proteins, lipids, and lipoproteins and lead to cell dysfunction by induction of oxidative stress, inflammation, and apoptosis (Rani et al., 2016; Redlich and Smolen, 2012; Mollazadeh et al., 2015; Wauquier et al., 2009). It has been indicated that several mechanisms are involved in the deleterious effects of oxidative stress and inflammation on metabolic bone disease. For example, it has been indicated that production of reactive oxygen species (ROS) increases the induction of apoptosis and autophagy in osteoblast (MC3T3-E1) cells (Liu et al., 2018). Also, it has been shown that high glucose and corresponding oxidative stress and inflammation triggers autophagy of MC3T3-E1 cells (Wang et al., 2016). Furthermore, it has been suggested that induced apoptosis in osteoblast cells can be regulated by mitigating mitochondrial dysfunction and ROS-mediated oxidative stress and inflammation (Sun et al., 2019).

Antioxidants are able to protect biological systems against ROS-induced cell injury. Some microbial strains and medicinal plants contain high amounts of antioxidants that can be effective in human health (Swain and Rautray, 2021). Polysaccharides with microbial and plant origin are important and useful compounds with potential biomedical properties (Song et al., 2020; Rjeibi et al., 2020). For example, it has been shown that *Lycium barbarum* polysaccharide can show protective effects against induced oxidative stress and inflammation in PC12 cells (Gao et al., 2015) and osteoblast cells (MC3T3-E1) by regulating miR-200b-3p/Chrd11/PPAR $\gamma$  signaling pathway (Jing et al., 2020). Furthermore, it has been indicated that polysaccharides from different sources can show protective effects against oxidative stress-induced cell mortality (Alencar et al., 2019; Olasehinde et al., 2020; Jayawardena et al., 2020).

Levan [ $\alpha$ -(2  $\rightarrow$  6)- $\beta$ -D-fructan] is produced by a wide range of bacterial strains and plant species which shows several potential physicochemical characteristics including high hydrophilicity, promising adhesiveness, and outstanding biocompatibility (González-Garcinuño et al., 2018). It has been also employed as a drug carrier in the form of nano-formulated structure to promote drug bioavailability (De Siqueira et al., 2020). Levan has been also reported to show antiviral (Gamal et al., 2020), antitumor (Queiroz et al., 2017), and antioxidant functions (Bouallegue et al., 2020).

On the other hand, the chemerin/CMKLR1 signaling pathway has been reported to play a key role in the adipogenesis and osteoblastogenesis of bone marrow stem cells (Muruganandan et al., 2010). It has been also reported that Resolvin E1 and chemokine-like receptor 1 can regulate bone preservation (Gao et al., 2013) under inflammatory conditions (El Kholy et al., 2018).

Although the biological activity of levan against some diseases have been reported, the exact mechanism by which levan induces its protective effects against expression of inflammatory mediators and oxidative stress through ChemR23 has not been fully explored. Therefore, the main objective and novelty of this study was to examine the protective effects of levan polysaccharide against lipopolysaccharide (LPS)-induced inflammation as a model and delineate its mechanism of action.

## 2. Materials and methods

### 2.1. Materials

Levan from *Erwinia herbicola*, MTT [3-(4, 5-Dimethylthiazol-2-yl)-2, 5-Diphenyltetrazolium Bromide] and lipopolysaccharide (LPS) were obtained from Sigma-Aldrich (Shanghai, China). All cellular culture materials were purchased from Gibco Co. (Shanghai, China).

### 2.2. Methods

#### 2.2.1. Cell culture and treatment

The osteoblast-like cells, MC3T3-E1, obtained from the cell bank of the Chinese Academy of Sciences (Shanghai, China), were cultured in the complete medium of  $\alpha$ -MEM containing 10% FBS in a humidified incubator with 5% CO<sub>2</sub> at 37 °C and 1% antibiotics. After reaching 70–80% confluency, the cells were cultured in differentiation medium ( $\alpha$ -MEM) supplemented with 10  $\beta$ -glycerol phosphate (mmol/L), L-ascorbic acid (50 mg/L), and dexamethasone (10 mmol/L) either alone or with different concentrations of LPS (0, 2, 5, 10, 20 and 50  $\mu$ g/mL) or levan (0, 10, 50, 100, 500 and 1000  $\mu$ g/mL) or left untreated (control) as the negative control for 72 h.

#### 2.2.2. Cell viability assay

The viability of MC3T3-E1 cells was examined by the MTT assay. Briefly, after treating the cells with LPS or levan (72 h), followed by removal of the culture median, MTT was added and the cells were incubated for another 4 h. The absorbance was then read at 570 nm after adding DMSO for 5 min employing a Microplate Reader (Bio-Rad, USA).

#### 2.2.3. Superoxide dismutase (SOD) and catalase (CAT) activity assays

After treatment and homogenization of the MC3T3-E1 cells, a fixed protein concentration was collected and the relative caspase-3, caspase-9, SOD, and CAT assays were carried out by relevant assay kits (Abcam, Shanghai, China) using a Microplate Reader (Bio-Rad, USA).

#### 2.2.4. Enzyme-linked immunosorbent assay (ELISA) for determination of interleukin-6 (IL-6) and tumor necrosis factor- $\alpha$ (TNF- $\alpha$ )

After treatment and homogenization of the MC3T3-E1 cells, a fixed protein concentration was collected and the relative quantities of interleukin-6 (IL-6) and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) were determined by ELISA kit (Abcam, Shanghai, China).

#### 2.2.5. Quantitative polymerase chain reaction (qPCR)

After treatment of the cells, the total RNA was extracted (TRIzol, Invitrogen), followed by doing reverse transcription (Transcriptor First Strand cDNA Synthesis Kit, Roche, USA). qPCR was then done with a One Step SYBR® master mix Kit (TaKaRa). The relative expression was then reported by using the  $2^{-\Delta\Delta Ct}$  method. The primers sequences are summarized in Table 1.

#### 2.3. Statistical analysis

The data were presented as the mean  $\pm$  standard deviation (SD) of five experiments and P-values were calculated with one-way analysis of variance (ANOVA) using SPSS software.

### 3. Results

#### 3.1. MTT assay

The alterations in the cell viability on treatment with LPS and levan in MC3T3-E1 cells at various concentrations at 72 h are shown in Fig. 1a and Fig. 1b, respectively. The cell viability

was enhanced after treatment with LPS concentrations from 0 to 10  $\mu\text{g}/\text{mL}$ , revealing a peak at 10  $\mu\text{g}/\text{mL}$  (Fig. 1a). The effect of LPS on the cell viability was reduced at concentrations over 10  $\mu\text{g}/\text{mL}$  (Fig. 1a). As the maximum value of the cell viability for LPS against MC3T3-E1 cells was detected at 10  $\mu\text{g}/\text{mL}$ , this concentration was chosen to be the potential LPS concentration for MC3T3-E1 cells (Fig. 1a). It was also found that the cell viability increased as the levan concentration was increased, demonstrating a peak and reducing after 50  $\mu\text{g}/\text{mL}$  at 72 h (Fig. 1b). In fact, the enhancement in the cell viability mitigated at levan concentrations higher than 50  $\mu\text{g}/\text{mL}$  at 72 h, a levan concentration of 50  $\mu\text{g}/\text{mL}$  was chosen for studying its protective effects against LPS-triggered inflammation and oxidative stress in MC3T3-E1 cells.

#### 3.2. SOD and CAT activity assay

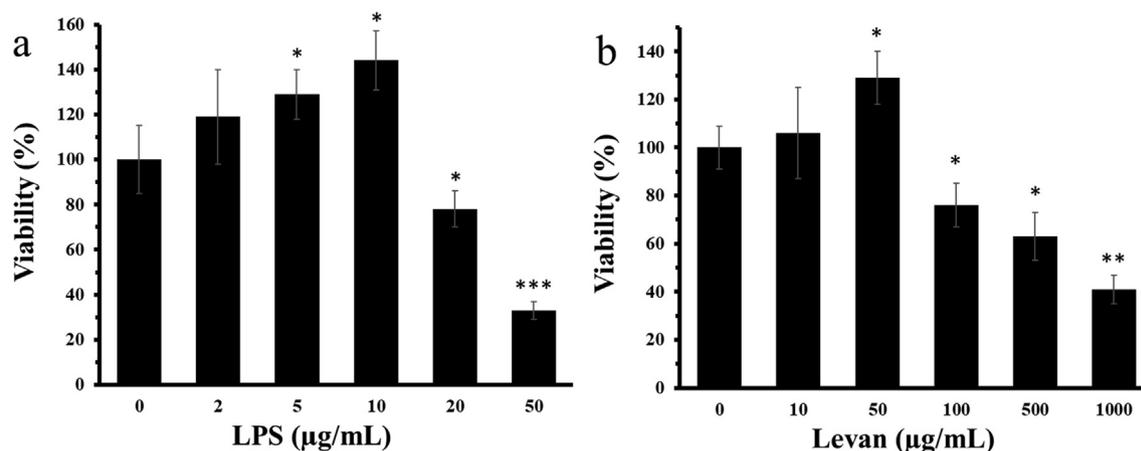

The SOD and CAT activity was assessed to explore the oxidative stress stimulated by LPS and the antioxidant properties of levan. The data indicated that levan can significantly increase the SOD (Fig. 2a) and CAT (Fig. 2b) activity in MC3T3-E1 cells ( $P < 0.05$ ) at 72 h. Afterwards it was observed that incubation of cells with LPS resulted in significant reduction of both SOD (Fig. 2a) and CAT (Fig. 2b) activity in MC3T3-E1 cells ( $***P < 0.001$ ), whereas treatment of the cells with levan resulted in the significant recovery of SOD and CAT activity at 72 h.

#### 3.3. IL-6 and TNF- $\alpha$ protein level assay

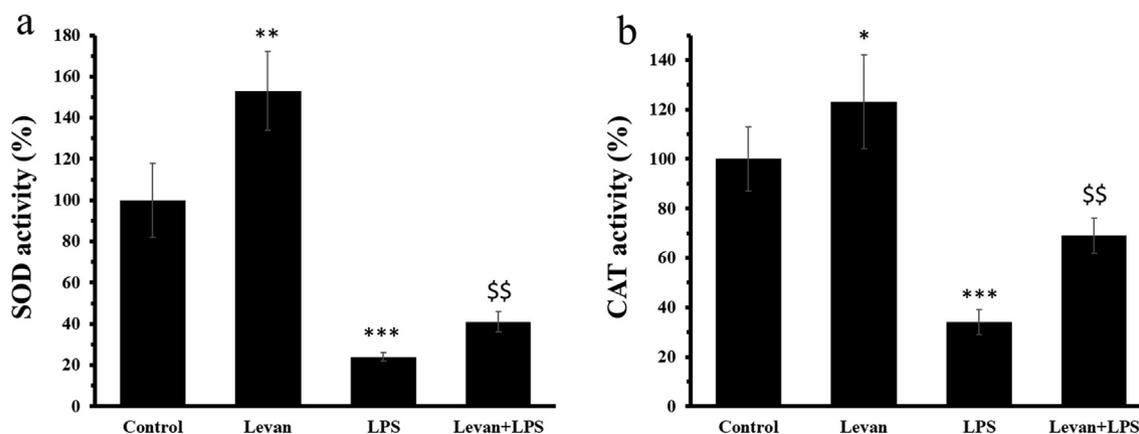

The protein levels of IL-6 and TNF- $\alpha$  were assessed to examine the inflammatory response triggered by LPS and the anti-

**Table 1** Primers used for qPCR.

Primer	Forward	Reverse
ChemR23	5'-ATGGAGTACGACGCTTACAACG-3'	5'-GGTGGCGATGACAATCACCA-3'

IL-6	5'-TGATGGATGCTTCCAAACTG-3'	5'-GAGCATTGGAAGTTGGGGTA-5'
$\beta$ -actin	5'-TCCTCCTGAGCGCAAGTAC-3'	5'-CCTGCTTGCTGATCCACATCT-3'

**Fig. 1** (a) The exploration of viability of MC3T3-E1 cells with increasing concentrations of lipopolysaccharide (LPS) for 72 h. (b) The exploration of viability of cells with increasing concentrations of levan for 72 h. Data are as the mean  $\pm$  SD, ( $n = 5$ ).  $*P < 0.05$ ,  $**P < 0.01$ ,  $***P < 0.001$  relative to control (0) group.

**Fig. 2** (a) The investigation of SOD activity in MC3T3-E1 cells. (b) The investigation of CAT activity in MC3T3-E1 cells. The cells were incubated either with levant (50  $\mu\text{g}/\text{mL}$ ) for 72 h or LPS (10  $\mu\text{g}/\text{mL}$ ) for 72 h or treated with levant and LPS for 72 h. Data are as the mean  $\pm$  SD, (n = 5). \* $P$  < 0.05, \*\* $P$  < 0.01, \*\*\* $P$  < 0.001 relative to control group, \$\$ $P$  < 0.01 relative to LPS-treated group.

inflammatory effects of levant. The results displayed that incubation of cells with LPS caused a profound enhancement in protein levels of IL-6 (Fig. 3a) and TNF- $\alpha$  (Fig. 3b) in MC3T3-E1 cells (\*\*\* $P$  < 0.001), whereas treatment of the cells with levant caused the significant reduction of IL-6 and TNF- $\alpha$  at protein level at 72 h.

### 3.4. qPCR assay

The mRNA expression levels of IL-6, TNF- $\alpha$ , and ChemR23 were assessed in MC3T3-E1 cells at 72 h. It was seen that incubation of cells with LPS for 72 h led to a significant increase in the mRNA expression levels of IL-6 (Fig. 4a), TNF- $\alpha$  (Fig. 4b), and ChemR23 (Fig. 4c), whereas the treatment of the cells with levant mitigated the LPS-induced upregulation of these genes at 72 h.

## 4. Discussion

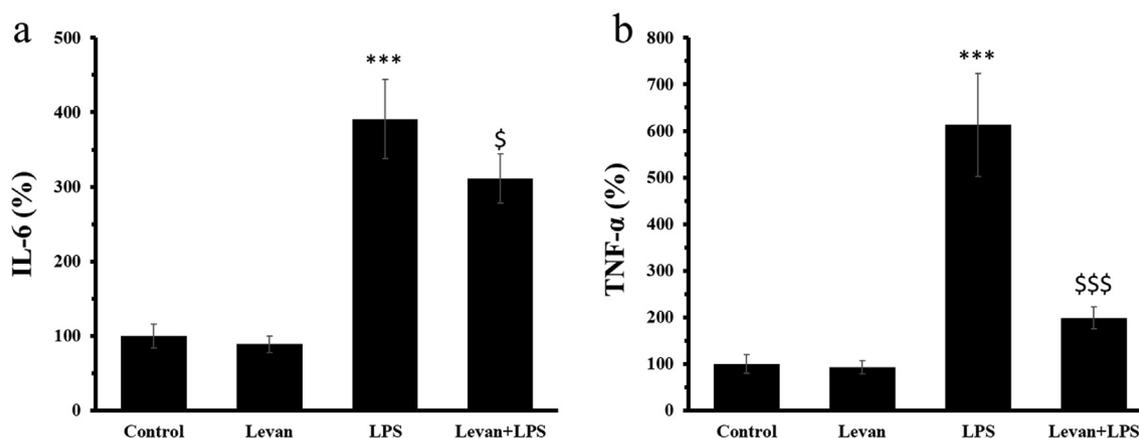

In the present study, we revealed that levant mitigates LPS-stimulated inflammation and oxidative stress in osteoblast

cells, as evidenced by decrease in the levels of pro-inflammatory cytokines and increase in the SOD and CAT activity. We also found that the ChemR23 expression at mRNA was enhanced after incubation of osteoblast cells with LPS which was mitigated by levant, suggesting that levant might trigger a protective impact by interacting with this receptor. In summary, these data indicated that levant can be a potential polysaccharide that exerts protective effects against LPS-induced osteoblast cells injury by preventing inflammatory feedback and increasing the rate of SOD and CAT in osteoblast cells.

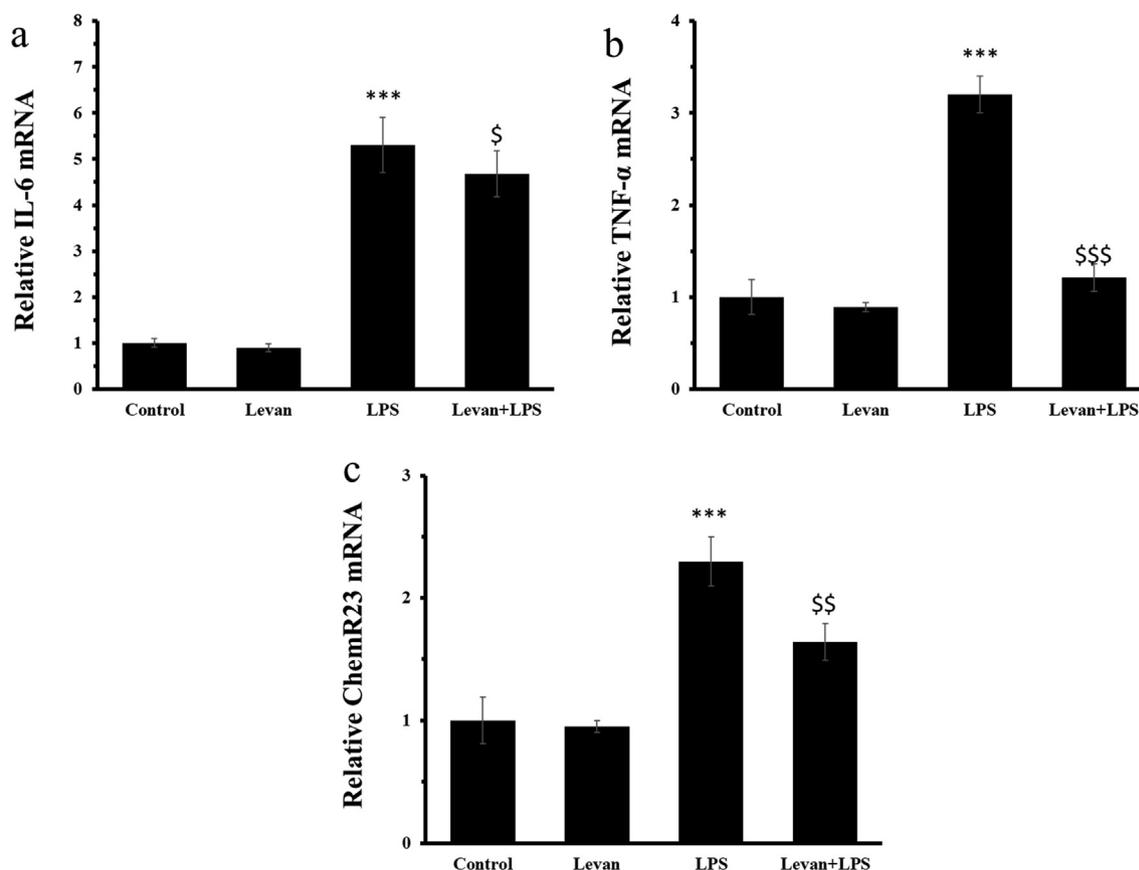

It has been reported that inflammation and oxidative stress result in bone loss (Braun and Schett, 2012). LPS has been used as a potential agent to induce oxidative stress and inflammation in osteoblast cells *in vitro* (Guo et al., 2014; Guo et al., 2015)

Levant has been shown to have potential antioxidant and anti-inflammatory activities (Abdel-Fattah et al., 2012; Srikanth et al., 2015).

Therefore, it was highly recommended to reveal the functional activities of levant in osteoblast cell injury.

**Fig. 3** (a) The protein level of IL-6 in MC3T3-E1 cells. (b) The protein level of TNF- $\alpha$  in MC3T3-E1 cells. The cells were incubated either with levant (50  $\mu\text{g}/\text{mL}$ ) for 72 h or LPS (10  $\mu\text{g}/\text{mL}$ ) for 72 h or treated with levant and LPS for 72 h. Data are as the mean  $\pm$  SD, (n = 5). \*\*\* $P$  < 0.001 relative to control group, \$ $P$  < 0.05, \$\$\$ $P$  < 0.001 relative to LPS-treated group.

The cells were incubated either with levan (50  $\mu\text{g}/\text{mL}$ ) for 72 h or LPS (10  $\mu\text{g}/\text{mL}$ ) for 72 h or treated with levan and LPS for 72 h. Data are as the mean  $\pm$  SD, (n = 5). \*\*\* $P$  < 0.001 relative to control group,  $^{\text{S}}P$  < 0.05,  $^{\text{SS}}P$  < 0.01,  $^{\text{SSS}}P$  < 0.001 relative to LPS-treated group.

Inflammatory cytokines lead to the inflammatory response against different stimuli. The levels of pro-inflammatory cytokines have been reported to be increased in the osteoblast cells in response to LPS (Guo et al., 2014; He et al., 2018). The inflammatory cytokines are believed to trigger bone resorption. Additionally, the neutralization of the cytokines resulted in the inhibition of the inflammatory feedback (Zhang et al., 2020). In the present study, incubation of osteoblast cells with LPS resulted in an increased mRNA and protein levels of IL-6 and TNF- $\alpha$  accompanied by a significant reduction in SOD and CAT activity, which were regulated by levan treatment. Therefore, levan may protect osteoblast cells from inflammatory injury by suppressing oxidative stress.

In fact, osteoblast cell inflammation is a crucial factor during osteolysis, and prevention of inflammation can play a key role in the bone resorption (Guo et al., 2018). We found that levan treatment protected osteoblast cells against inflammation through mitigation of the expression of pro-inflammatory mediators. Indeed, we used ELISA and qPCR analyses to explore LPS-induced inflammation in osteoblast cells. Our data showed that the LPS-induced expression of inflammatory cytokines was decreased by levan treatment. These data indicated that levan significantly protects osteoblast cells against LPS-induced bone destruction and osteolysis.

In addition, the overexpression of the ChemR23 by LPS was inhibited in the presence of levan, which contributed to

the protective influence of levan against osteoblast cell injury. It has been well-documented that osteoblast cells express ChemR23 receptor (Zhao et al., 2021; Muruganandan et al., 2010; Gao et al., 2013; El Kholy et al., 2018).

It has been also shown that some bioactive materials, including levan in the form of organic thin films can regulate the osteoblast cell signaling response which can be extended to study potential bioactive interfaces for tissue engineering (Axente et al., 2014).

Our data that levan can decrease the ChemR23 at mRNA level, assessed under inflammatory condition is, to the best of our knowledge, a novel outcome.

## 5. Conclusion

In conclusion, our results showed that levan protects the osteoblast cells from inflammation and oxidative stress induced by LPS. The mechanism was probably associated with the inhibition of ChemR23 and TNF- $\alpha$ /IL-6 inflammatory signaling pathways and modulation of oxidative stress. These outcomes suggested that levan might be a promising lipid mediator for the treatment of osteolysis. This study was the beginning of the process to determine the efficacy of levan to treat osteoporosis and in the future studies, the potential application of levan *in vivo* and to treat people with osteoporosis can be further explored in detail.
